From Advice to Influence: Examining How Ai Chatbots Shape User Perspectives Through Cognitive Reframing

Chandni VS
Mental Health Counsellor, KLE Law College, Bengaluru

***Abstract*—The widespread expansion of Artificial Intelligence (AI) chatbots across diverse domains of daily life has significantly altered the patterns of emotional seeking, information gathering and navigating decision-making processes. In addition to delivering factor information, contemporary AI chatbots increasingly play an expanding role in influencing user's perception, assess circumstances and derived meaning through cognitive reframing. This process entails restructuring of interpretation of experiences or events, thoughts or beliefs to encourage more adaptive and constructive responses. Synthesizing evidence from the fields of psychology, human- computer interaction, communication studies and AI ethics, this narrative review investigates the mechanisms and the role of AI chatbots in fostering cognitive reframing and subsequently shaping us perceptions and viewpoints.**

This review integrates findings that indicates conversational AI systems influence user through linguistic framing, emotional validation, perspective taking prompts, reflective inquiry and personalized feedback mechanisms. Such mechanisms mirror techniques commonly used in counselling and cognitive-behavioural practices, fostering cognitive restructuring, critical examination of assumptions and the development of more adaptive perspectives. Despite their potential to foster emotional well- being, they also significant concerns related to algorithmic bias, persuasive manipulation, dependency on AI assistance and the possible undermining of individual autonomy.

This review highlights both the potential benefits and ethical Arising from AI driven cognitive influence. It emphasizes the importance by advocating transparent design principles, comprehensive ethical frameworks and interdisciplinary inquiry to better assess the long-term psychological and societal effects of chatbot-mediated cognitive reframing. Such inquiries essential as AI increasingly functions as consequential agent in the formation of beliefs, perspectives and decision- making processes within the contemporary society.

***Index Terms*—Artificial Intelligence, Chatbots, Cognitive Reframing, Human- AI Interaction, User Perspectives.**

I. INTRODUCTION

The advent of Artificial Intelligence (AI) has fundamentally reconfigured the nature of human-technology interaction, most notably through the proliferation of conversational agents known as chatbots. Contemporary chatbot systems can engage users in nuanced, contextually adaptive and personalized dialogues, thereby enhancing the quality and effectiveness of human- computer communication. In contrast to earlier systems that were largely limited to information retrieval and task completion, contemporary chatbots have evolved into multifaceted tools that offer advice, emotional support, problem- solving guidance and assistance with everyday decision- making[1]. This evolution has positioned them as significant contributors to the processes through which individuals interpret experiences, develop perspectives and construct subjective meaning in their daily lives.

Among the psychological processes that contribute to the influence of AI chatbots, cognitive reframing occupies a particularly significant role. Defined as the cognitive restructuring of interpretations associated with situations, thoughts or experiences, cognitive reframing seeks to cultivate more adaptive and constructive patterns of thinking. Rooted in the principles of cognitive- behavioural therapy (CBT),

[1] Manole, A., Cârciumaru, R., Brînzaș, R., & Manole, F. (2024). Harnessing AI in Anxiety Management: A Chatbot-Based Intervention for Personalized Mental Health Support. Information, 15(12), 768. https://doi.org/10.3390/info15120768

cognitive reframing is widely recognized as an effective intervention for alleviating emotional distress, challenging maladaptive cognitions and enhancing psychological well- being[2]. Historically, cognitively reframing has been delivered through structure therapeutic interactions conducted by trained mental health practitioners. Nevertheless, advances in conversational AI have enabled chatbots to emulate aspects of this process by presenting various perspectives, promoting self- reflection, validating experiences, emotional validation and facilitating the reinterpretation of personal circumstances[3].

The increasing proliferation of AI chatbots has substantially expanded opportunities for individuals to engage in continuous, context- sensitive interactions with intelligent conversational agents. These systems are progressively being utilized for guidance across diverse domains including interpersonal relationships, education, career development, psychological well-being and routine decision- making. Rather than serving solely as information resources, AI chatbots increasingly shape users' cognitive appraisals, interpretive frameworks and decision- making processes. Consequently, they may foster adaptive outcomes such as increased emotional regulation, self-awareness, resilience and effective problem- solving skills. However, their growing influence also raises critical ethical and psychological concerns including algorithmic bias, persuasive manipulation, and excessive dependence on AI- generated recommendations[4].

The expanding influence of artificial intelligence on human cognition has intensified scholarly interest in understanding how conversational agents contribute to cognitive reframing and impact perspectives[5]. Integrative evidence from psychology, human-computer interaction, communication studies and AI ethics shows that this narrative review investigates the mechanism through which AI chatbots influence users' perspectives by facilitating cognitive reframing. It also examines the psychological benefits, broader implications, ethical considerations and emerging research priorities associated with AI- mediated cognitive influence[6]. Due to the rapid integration of conversational AI in everyday life, a comprehensive understanding of its role in shaping perspectives is essential for advancing both research and professional practice.

II. METHODOLOGY

2.2. Review design

Narrative review methodology was employed to critically analyze the current body of knowledge concerning the influence of artificial intelligence (AI) chatbots on users' perspectives through cognitive reframing. Unlike systematic reviews, which typically address highly specific research questions using predefined eligibility criteria and structured evidence synthesis, narrative reviews facilitate a comprehensive, interdisciplinary and interpretive understanding of evolving research topics by consolidating findings across diverse fields[7].

This approach was particularly appropriate because research at the intersection of AI chatbots, cognitive reframing and perspective formation remains in its developmental stages and spans multiple disciplines including psychology, artificial intelligence, cognitive

science and human- computer interaction, communication studies, digital health and AI ethics.

This narrative review enabled integration of recurring themes, theoretical frameworks, empirical evidence and conceptual perspectives to provide a comprehensive understanding of how conversational AI influences users' cognitive processes, emotional experiences, attitudes and decision- making abilities. The review adopted an interpretive approach to examine the mechanisms through which AI mediated dialogue facilitates cognitive reframing and contributes to perspective formation, instead of statistically synthesizing research outcomes.

2.2 Search Strategy

An extensive literature search was conducted to identify empirical and theoretical studies examining AI chatbots, cognitive reframing, conversational AI and perspective formation. To ensure comprehensive interdisciplinary coverage, bibliographic databases including Google Scholar, PubMed, Web of Science, PsycINFO, IEEE Xplore and the ACM Digital Library, as they collectively provide access to high- quality literature across psychology, digital health, artificial Intelligence, computer science and human- computing interaction. The search strategy combined controlled keywords with Boolean operators to optimize the identification of relevant publications. Search terms included combinations such as "Artificial Intelligence" AND Chatbots, "Conversational AI" AND Cognitive Reframing, "AI Chatbots" AND User Influence, "Large Language Models" AND Human AI- Interaction, "Generative AI" AND Decision-Making, "Chatbots" AND Cognitive Behavioural Therapy, "Conversational Agents" AND Perspective Taking, "AI Ethics" AND Persuasive Technology, "Human- AI Interaction" AND Behaviour Change and "Digital Mental Health" AND AI Chatbots.

The review predominantly considered literature published between 2015 and 2026 to capture developments associated with transformer– based language models and contemporary generative AI technologies. Foundational publications predating this period were also incorporated when necessary to contextualize core theoretical constructs including Cognitive Behavioural Therapy (CBT), cognitive reframing, Persuasive Technology and Human-Computer Interaction.

2.3 Inclusion Criteria

Publications were deemed eligible for inclusion when they fulfilled one or more of the following criteria:

- Published in the English language
- Appeared in peer- reviewed journals, conference proceedings, academic books or edited book chapters.
- Investigated AI chatbots, conversational agents, virtual assistants or conversation assistants based on large language models.
- Addressed topics related to human- AI interaction, digital mental health, persuasive technologies, user experience or conversational AI.
- Examined psychological constructs associated with cognitive restructuring, cognitive reframing, behavioural influence or decision- making, emotion regulation and perspective taking.
- Originated from relevant disciplines including psychology, cognitive science, psychiatry, education, healthcare, communication studies, artificial intelligence and computer science.
- Presented empirical evidence, conceptual models, theoretical analysis, narrative or systematic reviews, ethical discussions concerning AI-mediated cognitive influence.

Literature that was published in recent years was given preference to reflect upon the rapid evolution of conversational AI that was followed by the emergence of transformer- based large language models and generative AI technologies. In spite of this, the seminal studies that focused primarily on theoretical foundations of Cognitive Behavioural Therapy (CBT)[8], persuasive technology[9], cognitive reframing, and the Computers Are Social Actors (CASA) paradigm[10] were maintained because of their enduring relevance to the topic.

[10] Nass, C., Steuer, J., & Tauber, E. R. (1994). Computers are social actors. *Proceedings of the SIGCHI Conference on Human Factors in Computing*

2.4 Exclusion Criteria

Publications were excluded if they satisfied the following criteria:

- Focused solely on the technical aspects of chatbot architecture, machine learning optimization, algorithm design or software engineering without addressing psychological, behavioural or human-centered outcomes.
- Comprised non- scholarly sources including opinion articles, newsletters, blogs, magazine publications or other materials that had not undergone peer review.
- Did not examine conversational AI, cognitive reframing or related processes associated with user perspective formation.
- Were published in languages other than English.
- Were identified as duplicate publications across the selected bibliographic databases.
- Concentrated primarily on hardware development, robotics or speech recognition technologies without evaluating users' cognitive, emotional, attitudinal or behavioural outcomes.
- Provided insufficient methodological information or demonstrated limited theoretical relevance to the aims of the review.
- Investigated conventional decision- support systems or automated technologies that lacked conversational interaction with users.

Following the application of the inclusion and the exclusion criteria, the selected studies were subjected to critical review and an in- depth thematic synthesis[11]. The literature was organized into key thematic categories including the evolution of AI chatbots, the conceptual foundations of cognitive reframing, ethical and societal considerations, mechanisms underlying AI- mediated perspective formation, current research gaps and practical applications across multiple contexts. This interpretative synthesis enabled the development of a cohesive understanding of the current evidence base while informing the conclusions, practical implications and future research agenda proposed in the present review.

III. BRIEF LITERATURE REVIEW

Artificial Intelligence (AI) chatbots have emerged as one of the most transformative applications of artificial intelligence, fundamentally altering how individuals access information, seek emotional support and make decisions. At first, they developed as automated systems to handle routine interactions and systems to answer user queries, then the modern chatbots evolved into sophisticated conversational systems capable of engaging in contextually relevant, emotionally nuanced and highly personalized dialogues. Recent advancements in Natural Language Processing (NLP), deep learning and Large Language Models (LLMs) have significantly enhanced the conversational abilities of AI systems, enabling them to understand user intent, maintain contextual continuity and generate responses that closely resemble human communication.

This evolution has expanded the role of AI chatbots beyond task- oriented assistance to include functions traditionally associated with human advisors, educators and mental health professionals. The growing psychological influence of AI chatbots has attracted increasing scholarly attention across psychology, human- computer interaction, communication studies, cognitive sciences, healthcare and AI ethics. Existing literature suggests that conversational AI does not merely transmit information, but can actively shape cognitive processes through mechanisms such as reflective questioning, emotional validation, personalized feedback and perspective- taking. The following review synthesizes current literature by examining the historical evolution of AI chatbots, the psychological theories underpinning cognitive reframing, the opportunities and ethical challenges associated with AI- mediated cognitive influence and mechanisms through which conversational AI facilitates perspective change.

3.1 Evolution of AI Chatbots

The evolution of AI chatbots reflects broader advancement in artificial intelligence and NLP over the past six decades. Early conversational systems are

Systems (CHI '94), 72–78. https://doi.org/10.1145/191666.191703

[11] Braun, V., & Clarke, V. (2006). Using thematic analysis in psychology. *Qualitative Research in Psychology*, *3*(2), 77–101. https://doi.org/10.1191/1478088706qp063oa

primarily rule- based programs designed to simulate limited human conversations through predefined scripts and pattern- matching algorithms. One of the earliest and most influential examples could be ELIZA, developed by Joseph Weizenbaum in 1966[12]. ELIZA simulated a Rogerian psychotherapist by transforming user statements into reflective questions using simple linguistic rules although ELIZA possessed no genuine understanding of language, many users reported feeling emotionally understood, a phenomenon later termed the ELIZA effect, wherein the individuals attribute intelligence, intentionality and empathy to computer programs despite knowing that they are interacting with machines. This observation provided one of the earliest indications that conversational systems could exert psychological influence beyond the technical capabilities.

Subsequent generations of conversational agents including PARRY[13], ALICE (Artificial Linguistic Internet Computer Entity (ALICE)[14] and various rule-based virtual assistants developed during the 1990s and early 2000s, that demonstrated improvements in conversational flexibility, but remained constrained by manually- programmed knowledge bases and limited contextual understanding. These systems were primarily employed for customer service, and information retrieval and educational support with minima capacity of meaningful dialogue or adaptive interactions.

A major transformation occurred with the emergence of machine learning and neural network- based NLP. Instead of relying solely on handcrafted rules, conversational systems began learning linguistic patterns from large datasets, enabling greater flexibility in understanding user intent and generating more coherent responses. The introduction of transformer- based architectures by Vaswani et al. (2017)[15], followed by the development of LLM's such as BERT, GPT-3, GPT- 4, Claude, Gemini and Llama, represented a paradigm shift in conversational AI. These models are capable of processing extensive contextual information, adaptive responses, generating human- like language across diverse domains by making conversations substantially more dynamic and personalized than the previous generation of chatbots.

Modern AI chatbots differ fundamentally from earlier systems in their ability to engage in sustained, context-aware conversations. Rather than providing answers to individual queries, they maintain conversational continuity recognize emotional cues expressed through language, tailor responses according to user preferences, conversation history and previous interactions. These capabilities have enabled chatbots to function as virtual tutors, productivity coaches, healthcare assistants and mental health support tools. Applications such as Woebot, Youper and Wysa incorporate evidence- based psychological principles, particularly Cognitive Behavioural therapy (CBT), mindfulness and motivational interviewing to help users manage anxiety, stress, depression and emotional challenges[16]. Recent studies suggest that AI chatbots should be viewed as cognitive intermediaries that actively participate in users thinking processes rather than mere information retrieval tools[17]. AI systems influence attention, emotional appraisal, interpretation and decision- making by framing information in particular ways and encouraging users

to reconsider existing beliefs through repeated conversational interactions. This shift from providing advice to shaping perspectives marks a significant evolution in the role of conversational AI and forms the foundation of our understanding how cognitive reframing operates within human AI interactions.

3.2 Theoretical Foundations

Understanding how chatbots shapes user perspectives through cognitive reframing predominantly require an examination of psychological and communication theories that underpin human cognition and human-technology interaction. The influence of AI on users is deeply rooted from theories of cognitive psychology, social psychology, psychotherapy and human-computer interaction, even though it is a technological innovation. These theories explain why individuals respond to AI generated conversations in ways that resemble interactions with human advisors and how conversation exchanges can modify interpretations, decision- making and attitudes. Three theoretical perspectives are particularly relevant to this present review: Cognitive Reframing Theory, Human- AI Interaction Theory and Persuasion Theory.

3.2.1 Cognitive Reframing Theory

Cognitive reframing, which is also known as cognitive restructuring, is a central component of CBT, developed by Aaron T. Beck[9] during the 1960s and was influenced by Albert Ellis's REBT[18]. The theory proposes that emotional reactions and behavioural responses are determined not solely by external events but by the way individuals interpret those events. Maladaptive interpretations, generally referred to as cognitive distortions, contribute to psychological distress, meanwhile adopting more balanced and realistic perspectives promotes emotional well- being and adaptive behaviour.

The conversational nature of AI chatbots makes them particularly suitable for facilitating cognitive reframing. Modern conversational agents frequently encourage users to examine their assumptions through reflective questioning, challenge negative automatic thoughts and provide alternative interpretations of situations and promote problem- solving strategies. These interactions resemble therapeutic techniques such as Socratic questioning, cognitive restructuring, and guided discovery commonly employed in CBT. For instance, when users express catastrophic or self-critical thoughts, the chatbots may respond by encouraging them to consider additional evidence, explore more balanced perspective or identify cognitive biases. Consequently, AI systems increasingly function as digital facilitators of cognitive reframing, influencing how users interpret personal experiences and make subsequent decisions.

3.2.2 Human AI- Interaction Theory

The psychological influence of conversational AI is further explained by theories of human-computer interaction particularly the Computers Are Social Actors (CASA) paradigm proposed by Reeves and Nass (1996)[19]. According to this theory, individuals naturally apply the same social rules, interpersonal behaviours and expectations that they use during interactions with other people. Even when users are fully aware that they are communicating with the machine, they frequently respond as technology possesses social characteristics such as empathy, competence, politeness and trustworthiness.

Recent advancements in LLMs have subsequently increased this social realism. Contemporary AI chatbots can maintain long conversations, recognize emotional cues expressed in text, adapt emotional responses to individual users and provide contextually relevant guidance. These capabilities strengthen users' trust and engagement while simultaneously increasing the persuasive potential of chatbot interactions. The CASA framework therefore provides an important explanation for why users may internalize perspectives suggested by AI chatbots. When conversational AI is perceived as knowledgeable, understanding and supportive, users become more receptive to alternative interpretations offered during dialogue. Consequently, conversational AI functions tool as a social actor rather than merely a technological tool, which is significantly capable of participating in

[18] Ellis, A. (1962). *Reason and emotion in psychotherapy*. Lyle Stuart.

[19] Reeves, B., & Nass, C. (1996). *The media equation: How people treat computers, television, and new media like real people and places*. Cambridge University Press.

cognitive and emotional processes traditionally associated with interpersonal communication.

3.2.3 Persuasion Theory and Cognitive Influence

The ability of AI chatbots to influence users' perspectives is also supported by the theories of persuasion and behavioural change. Persuasion generally refers to the process through which communication alters attitudes, beliefs, intentions or behaviours without coercion. In the context of conversational AI, persuasion typically occurs through the framing of information, reflective questioning, conversational guidance and repeated exposure to particular viewpoints instead of involving in direct attempts to convince users. One of the most influential frameworks in this area is Fogg's Persuasive Technology Theory (2003)[10], which argues that interactive technologies can be intentionally designed to change consumers' attitudes and behaviours. According to Fogg, computers can function as persuasion tools by simplifying complex decisions, providing timely feedback, encouraging desired behaviours and reinforcing positive actions. AI chatbots exemplify these persuasive functions by offering personalized suggestions, encouraging healthier habits, reminding users of goals and presenting alternative ways of interpreting situations.

Closely related concepts from behavioural economics such as Nudge Theory proposed by Thaler and Sunstein (2008)[20], further explains how conversational AI can shape decision- making without restricting user choice. By asking reflective questions, emphasizing certain interpretations or highlighting potential consequences, AI chatbots may gently guide users toward cognitive or behavioural outcomes. This occurs implicitly, while making users unaware of the extent to which conversational framing affects their judgments.

The Elaboration Likelihood Model (ELM) of persuasion[21] also provides valuable insight into AI-mediated influence. The model posits that individuals process persuasive information through either a central route, involving careful evaluation of arguments or a peripheral route relying on cues such as familiarity, credibility and trust. As many users perceive AI chatbots as knowledgeable and objective, recommendations generated by conversational AI may be accepted with relatively limited critical evaluation, especially in situations involving emotional distress, uncertainty or limited prior knowledge.

3.3 AI Chatbots Performing Cognitive Reframing

The capacity of AI chatbots to influence users extends beyond providing factual information or answering questions. Contemporary conversational AI systems engage users in dialogues that support reflection, reinterpretation of experiences and modification of existing beliefs. These interactions resemble cognitive reframing, which is a psychological process wherein the individuals are guided to reconsider the meaning they assign to thoughts, emotions or life events. Unlike traditional therapeutic settings, where reframing is facilitated by trained mental health professionals, AI chatbots perform a similar function through language-based interactions generated by large language models. Emerging evidence suggests that this influence is achieved through several interrelated conversational mechanisms that collectively shaped users' cognitive and emotional responses.

3.3.1 Reflective Questioning and Guided Self-Reflection

One of the most prominent mechanisms employed by AI chatbots is reflective questioning. Rather than immediately providing solutions, advanced conversational systems often encourage users to examine their own assumptions by posing open- ended questions such as "What evidence supports this belief?", "Could there be another explanation?" or 'How would you advise a friend in the same situation?" These prompts resemble the Socratic questioning techniques widely used in CBT to identify

[20] Thaler, R. H., & Sunstein, C. R. (2008). *Nudge: Improving decisions about health, wealth, and happiness*. Yale University Press. Thaler, R. H., & Sunstein, C. R. (2008). *Nudge: Improving decisions about health, wealth, and happiness*. Yale University Press.

[21] Petty, R. E., & Cacioppo, J. T. (1986). The elaboration likelihood model of persuasion. In *Communication and persuasion: Central and peripheral routes to attitude change* (pp. 1–24). Springer. https://doi.org/10.1007/978-1-4612-4964-1_1

cognitive distortions and promote metacognitive awareness[22].

Reflective questioning encourages users to slow down automatic thought processes and critically evaluate their interpretations before arriving at conclusions. Research in digital mental health has shown that such guided self- reflection improves emotional awareness, reduces cognitive rigidity and supports adaptive coping strategies. Consequently, the reframed perspective is more likely to be internalized because it emerges through the users' own reasoning process rather than external persuasion.

3.3.2 Emotional Validation and Empathetic Communication

Effective cognitive reframing requires that individuals first feel understood before they are willing to reconsider their perspectives. Accordingly, modern AI chatbots frequently begin conversations by acknowledging users' emotions through statements that communicate empathy and validation. Responses such as "That sounds like a difficult experience" or "It is understandable to feel overwhelmed in this situation," help establish psychological safety and reduce perceived judgment. Although AI systems do not experience emotions themselves, advances in natural language processing enable them to detect emotional cues expressed in users' language and respond in ways that resembles empathetic communication. Studies have reported that perceived empathy increases users' trust, engagement and willingness to disclose personal concerns, thereby strengthening the effectiveness of subsequent cognitive reframing interventions[5]. Emotional validation therefore serves as a foundation upon which alternative interpretations can be introduced without appearing dismissive of the users' experiences.

Nevertheless, researchers cautioned that simulated empathy differs fundamentally from genuine empathy as AI- generated validation is algorithmically produced rather than emotionally experienced this remains an ongoing debate regarding the authenticity, potential psychological consequences and ethical implications and prolonged reliance on machine-generated emotional support.[23]

3.3.3 Alternative Perspective Generation

A defining characteristic of cognitive reframing is the presentation of alternative ways of interpreting events. Contemporary AI chatbots excel at generating multiple perspectives as large language models are trained on extensive and diverse textual cognitive reframing numerous perspectives, communication styles and cultural contexts. Conversational AI can encourage users to examine situations from different emotional, social or practical viewpoints instead of reinforcing a single interpretation[3]. For instance, a user who perceives failure as evidence of personal inadequacy may receive responses encouraging them to reinterpret the experience as an opportunity for learning, skill development or resilience. Similarly, interpersonal conflicts may be reframed by considering the motivations, constraints or emotions experienced by other individuals involved. Such perspective broadening reduces cognitive rigidity and promotes more flexible thinking, which is associated with improved emotional regulation and adaptive decision- making.

3.3.4 Personalized Conversational Adaptation

Recent developments in conversational AI have enabled chatbots to generate personalized responses by dynamically incorporating context information from ongoing interactions. Modern systems adapt explanations, tone, examples and recommendations according to users expressed concerns, communication style and previous conversational history, instead of producing identical responses for every user. Personalization facilitates cognitive reframing since users perceive individualized responses as more credible, relevant and meaningful than generic advice. According to studies, persuasive communication consistently demonstrates the personally relevant messages are processed more

[22] Fitzpatrick, K. K., Darcy, A., & Vierhile, M. (2017). Delivering cognitive behavior therapy to young adults with symptoms of depression and anxiety using a fully automated conversational agent (Woebot): A randomized controlled trial. *JMIR Mental Health*, *4*(2), e19. https://doi.org/10.2196/mental.7785

[23] Sedlakova, J., & Trachsel, M. (2023). Conversational artificial intelligence in psychotherapy: A new therapeutic tool or a potential risk? *The American Journal of Bioethics*, *23*(5), 4–13. https://doi.org/10.1080/15265161.2022.2048739

deeply and more likely to influence attitudes and behavioural intentions[24]. Within AI- mediated conversations, personalization enables reframing strategies to align with users' existing beliefs, experiences and values. This increases their psychological impact. Still personalized conversational systems raise important ethical concerns. Excessive personalization may inadvertently reinforce existing biases, increase users' dependence on AI- generated guidance or create algorithmic echo chambers. These considerations highlight the importance of balancing personalization with transparency and user autonomy.

3.4 Cognitive Reframing Shaping User Perspectives

Cognitive reframing becomes significant in the conversation contexts since the changes in the interpretation of the experience can extend beyond immediate emotional relief to influence broader perceptions, behavioural intentions and judgments. When users repeatedly engage with AI chatbots which provide alternative interpretations, personalized explanations and reflective prompts, the interaction may influence how they subsequently understand themselves, situations and other people. Therefore, the significance of AI- mediated reframing lies in its potential to shape wider patterns of perspective formation and not just in the capacity to modify individual thoughts.

3.4.1 Influence on Interpretation of Personal Experiences

Individuals rarely respond to events solely on the basis of objective circumstances; their responses are influenced by the meanings they assigned to those events[25]. Cognitive reframing can modify the meanings by introducing multiple interpretations. In chatbot interactions, users may describe an experience and receive responses that encourage them to consider explanations beyond their initial interpretation. For example, if a person interprets academic failure as a proof of personal inadequacy, they may be motivated to look for situational factors, the possibility of learning from the experience or the limitations in preparation. Such reframing may reduce rigid, biased or self- critical interpretations and facilitate more balanced appraisal.

3.4.2 Influence on Emotional Appraisal and Regulation

Cognitive appraisal is closely associated with emotional responses. The same stimulus may generate emotional reactions depending on whether it is interpreted as a threat, opportunity, challenge, or loss[26]. By encouraging users to reconsider the meaning associated with a stimulus, chatbots may eventually facilitate cognitive reappraisal- an emotional regulation strategy associated with reduced negative affect and grater psychological resilience[27]. Conversational systems that combine emotional validation with alternative interpretations can potentially help users move from immediate emotional reactions towards more reflective appraisal. For instance, reframing an interpersonal disagreement from an indication of rejection to a communication difficulty may reduce perceived threat and encourage constructive problem- solving. This is particularly relevant to digital mental health applications, where conversational agents have been designed to support emotional regulation and cognitive coping strategies.

3.4.3 Influence on Beliefs and Attitudes

Repeated exposure to particular explanations or interpretative frames can contribute to changes in attitudes and beliefs. Conversational AI is potentially influential in this regard because it does not merely present information; rather, it organizes information into narratives and responses that make certain interpretations more salient. In situations where users repeatedly encounter a particular framing of an issue,

[24] Tam, K. Y., & Ho, S. Y. (2005). Web personalization as a persuasion strategy: An elaboration likelihood model perspective. *Information Systems Research*, *16*(3), 271–291. https://doi.org/10.1287/isre.1050.0058

[25] Lazarus, R. S., & Folkman, S. (1984). *Stress, appraisal, and coping*. Springer Publishing Company.

[26] Gross, J. J. (2002). Emotion regulation: Affective, cognitive, and social consequences. *Psychophysiology*, *39*(3), 281–291. https://doi.org/10.1111/1469-8986.3930281

[27] Gross, J. J., & John, O. P. (2003). Individual differences in two emotion regulation processes: Implications for affect, relationships, and well-being. *Journal of Personality and Social Psychology*, *85*(2), 348–362. https://doi.org/10.1037/0022-3514.85.2.348

that framing may become easier to retrieve and subsequently influence judgments[28]. This is significantly crucial when users approach AI systems with uncertainty and limited prior knowledge. Thus, the perceived competence and neutrality of the chat bot may increase acceptance of its recommendations.

3.4.4 Influence on Decision- Making and Problem-Solving

AI chatbots are increasingly used as decision- support tools in education, employment, relationships, healthcare and everyday problem- solving. Their influence operates largely via cognitive reframing by altering how users mentally represent and bound position problem prior to chosen a cause of action[29]. For instance, a user considering a career change may initially frame the decision as a choice between 'security' and 'failure'. A chatbot may broaden the decision by introducing factors such as personal values, long- term goals, transferable skills, financial considerations and alternative career pathways. The chatbot has not necessarily made the decision for the user, instead it has altered the cognitive representation of the decision problem.

3.4.5 Influence on Self- Perception and Personal Narratives

An important but a comparatively unexplored consequence of repeated cognitive reframing is its potential effect on self- perception, individuals conduct narratives about themselves based on how they interpret their successes, relationships, failures and personal characteristics[30]. Conversational AI can participate in this process by repeatedly reflecting, reorganizing and labelling users' descriptions of their experiences. If a user who repeatedly describe themselves as "unsuccessful" may receive responses that distinguish a specific unsuccessful outcome from a global judgment about personal ability, over time such reframing may encourage a more differentiated self- concept.

3.4.6 Influence on Behaviour

Changes in perspective can ultimately affect behaviour. If an individual is interpreting a situation differently, it leads to a circumstance where the perceived options, expected consequences and risks associated with the situation may also differ accordingly[31]. AI chatbots can therefore influence behaviour indirectly by first modifying the cognitive frame through which users evaluate a situation. The chatbot's influence functions through a sequence in which conversations affect interpretation, interpretation alters appraisal and appraisal leads to behavioural intention.

3.5 Applications of AI- Mediated Cognitive Reframing

The application of conversational AI has expanded considerably beyond information retrieval and routine task automation. As AI chatbots become increasingly capable of understanding conversational context and generating personalized responses, they are being incorporated into domains involving learning, emotional support, decision- making, health and behavioural change. Accordingly, the significance of chatbots lies in their capability to frame information, present alternative interpretations and encourage reflection.

3.5.1 Mental Health and Psychological Support

Mental health is one of the most extensively studied applications of conversational AI- mediated cognitive technologies. Chatbots have been developed to provide psychoeducation, mood monitoring, emotional support, mindfulness exercises, behavioural activation and elements of CBT. Early evidence from Woebot demonstrates the feasibility of delivering CBT informed conversational support through automated agent, with users reporting reductions in symptoms of depression and anxiety following interaction with the

[30] McAdams, D. P. (2001). The psychology of life stories. *Review of General Psychology*, *5*(2), 100–122. https://doi.org/10.1037/1089-2680.5.2.100

[31] Ajzen, I. (1991). The theory of planned behavior. *Organizational Behavior and Human Decision Processes*, *50*(2), 179–211. https://doi.org/10.1016/0749-5978(91)90020-T

system[32]. Cognitive reframing within the systems may occur when users are encouraged to identify negative automatic thoughts, develop more balanced interpretations of stressful experiences and examine alternative explanations.

3.5.2 Education and Learning

Conversational AI is being used as a learning assistant, tutor and academic support tool[33]. In educational context, cognitive reframing can occur when chatbots help students reinterpret academic difficulties, adopt an alternative approach to learning and challenge productive assumptions. AI tutors can also facilitate metacognitive reflection by asking learners to explain their reasoning, consider alternative solutions and identify areas of uncertainty. This can support self-regulated learning by shifting students from passive information consumption towards active reflection and problem- solving.

3.5.3 Healthcare and Patient Communication

AI mediated support can be used and explored for patient education,

health information, symptom guidance, health behaviour changes and treatment support as cognitive reframing may help users integrate health- related information in ways that encourage constructive engagement in treatment and self- management[34]. Patients may interpret a chronic health condition as an irreversible limitation on everyday life. A chatbot may provide information and encourage the user to distinguish between aspects of the condition that cannot be changed and behaviours or lifestyle factors that remain manageable. Users can ask questions repeatedly, receive explanations without fear of embarrassment or judgment and request clarification. However, healthcare is a high-stakes domain in which inaccurate information or inappropriate reassurance may have serious consequences. Therefore, cognitive reframing should never be used to minimize symptoms, replace clinical decision- making or discourage professional consultation.

3.5.4 Career Guidance and Workplace Decision-Making

AI chatbots are increasingly used for career exploration, preparation for professional development, coaching and workplace problem- solving. Cognitive reframing can contribute to these applications by helping users reinterpret professional experiences and identify alternate perspectives on workplace challenges. An employee who interprets criticism from a supervisor solely as evidence of incompetence may be encouraged to consider whether the feedback identifies specific skills that can be developed, or the individual experiencing career uncertainty may be guided to examine personal values, financial considerations, transferable skills and alternative career pathways rather than viewing the situation as a simple choice between success and failure[35]. AI recommendations should supplement rather than replace informed human judgment and professional career counselling.

3.5.5 Relationship and Interpersonal Support

Individuals use conversational AI to discuss interpersonal conflicts, family difficulties, romantic relationships and communication problems. Chatbots can provide alternative interpretations of interpersonal events and encourage users to consider perspectives other than their own[36]. An individual who interprets a delayed response from a friend as deliberate rejection

[35] Savickas, M. L. (2005). Career construction theory: A developmental discourse of accenting adaptability and narrative identity. In S. D. Brown & R. W. Lent (Eds.), *Career development and counseling: Putting theory and research to work* (pp. 42–70). John Wiley & Sons.

[36] De Freitas, J., Uğuralp, A. K., & Cikara, M. (2024). AI companions and human psychology: Opportunities, challenges, and ethical guardrails.

may be encouraged to consider alternative explanations such as competing responsibilities, misunderstanding or communication preferences. The primary potential benefit is perspective broadening. By temporarily distancing oneself from an emotionally charged interpretation, conversational AI may facilitate more reflective responses. However, responses may unintentionally reinforce one- sided narratives, encourage decisions based on incomplete information or validate inaccurate assumptions.

3.5.6 Behaviour and Health Promotion

Conversational AI has also been investigated as a tool for promoting behavioural change in areas such as physical activity, medication adherence, smoking cessation, nutrition, sleep and stress management[37]. Behaviour- change chatbots frequently combine reminders, goal setting, motivational messages, feedback and personalized dialogue. If physical activity may be framed not merely as a task that must be completed but as a means of improving energy, long- term functioning or mood. The ethical boundary between supportive persuasion and manipulation becomes particularly important when AI systems are designed to influence repeated behavioural choices.

3.5.7 Social and Emotional Support

Beyond formal mental health applications, users increasingly interact with AI companions for companionship, emotional expression, conversation and everyday reflection[38]. The perceived availability and non- judgmental nature of conversational AI may make it attractive to individuals seeking a space to articulate thoughts and feelings. Unlike conventional information technologies, conversational AI can respond in an emotionally attuned and personalized manner, creating an interaction that may be experienced as especially meaningful. The underlying design logic can be conceptualized summarized as: "minimize resistance, maximize accommodation and sustain engagement". Such a design orientation may enhance user satisfaction in conversation continuity; however, when applied to psychologically sensitive interactions, excessive accommodation may reinforce existing beliefs rather than encourage critical reflection. Although this statement should not be interpreted as a literal or universal design principle of AI, it captures an important concern surrounding highly accommodating conversational systems.

3.5.8 Decision Support and Everyday Problem-Solving

One of the broadest applications of AI- mediated cognitive reframing is everyday decision support. Users increasingly consult conversational AI when comparing options, resolving practical problems, planning activities or evaluating choices. Chatbots can augment decision- making by helping users identify assumptions, consider potential consequences, generate alternatives and organize relevant information[39]. The principal contribution of cognitive reframing in decision support is therefore not necessarily to determine the correct decision but to alter how the decision problem is conceptualized. Nevertheless, the increasing use of AI as a decision-support system also creates a risk of automation bias, as users place excessive confidence in machine-generated recommendations[40]. This is particularly problematic when users interpret the apparent fluency of an AI response as evidence of factual accuracy or expertise. Thus, effective implementation requires mechanisms that encourage users to verify important information and retain responsibility for consequential decisions.

3.7 Risk and Ethical Challenges

Although AI- mediated cognitive reframing offers potential benefits for self- reflection, decision-making, and emotional regulation, its ability to influence how users interpret experiences, creating significant psychological, technological and ethical risks. Unlike conventional information systems, conversational AI can interact continuously with users, influence perspectives through natural language and personalized responses. Eventually, the risks associated with these systems extend beyond inaccurate information to include concerns regarding autonomy, privacy, psychological dependency and accountability.

3.7.1 Algorithmic Bias and Persuasive Manipulation

AI chatbots can influence users' perspectives through the combined effects of algorithmic bias and persuasive communication. AI systems are trained on large datasets that may contain social, cultural, gender, ideological and other forms of biases[41]. Eventually, the alternative perspectives generated during cognitive reframing may not always be neutral or universally appropriate. Chatbots may unintentionally reproduce stereotypes, dominant viewpoints, or culturally-specific assumptions while presenting them as reasonable interpretations. This is significant when users depend on AI to understand sensitive issues involving identity, mental health,

The risk is further augmented when AI systems are optimized for engagement or user satisfaction. Systems that consistently agrees with users or provides responses to maintain conversation may unintentionally reinforce existing beliefs rather than challenge them. Mitigating these concerns requires diverse and carefully curated training data, transparent system design, mechanisms that communicate uncertainty and bias testing[42]. AI systems should also be designed to present appropriate alternative perspectives rather than automatically reinforcing users' existing assumptions.

3.7.2 Hallucination and Misinformation

AI chatbots frequently generate inaccurate or fabricated information while presenting it with high linguistic confidence- a phenomenon known as hallucination[43]. When such confabulated facts or erroneous logic are embedded within a cognitive reframing, users may develop inaccurate interpretations of their experiences or make poorly informed decisions. This is particularly problematic in sensitive domains such as mental health, interpersonal relationships and clinical healthcare. Accuracy and appropriate uncertainty are therefore essential when AI systems provide perspective- changing decisions.

3.7.3 Dependency on AI and Loss of Human Judgment

The continuous availability and the personalized nature of chatbots may encourage users to depend excessively on AI for emotional reassurance, decision-making and interpretation of experiences. Seeking validation repeatedly from chatbots may reduce independent reflection and increase psychological reliance on the system[44]. Therefore, AI- mediated reframing should support users' cognitive autonomy rather than becoming their primary source of emotional or cognitive validation. Users may disclose highly personal information while seeking emotional support or advice from chatbots. Such conversations may contain sensitive psychological, health, relational or personal information. Clear privacy practices and informed users consent are essential when conversational AI is used for psychologically sensitive interactions.

3.7.4 Transparency and Accountability

Users may not fully understand how AI- generated responses are produced, who is responsible and when

[41] Bender, E. M., Gebru, T., McMillan-Major, A., & Shmitchell, S. (2021). On the dangers of stochastic parrots: Can language models be too big? *Proceedings of the 2021 ACM FAccT Conference*, 610–623. https://doi.org/10.1145/3442188.3445922

[44] Sedlakova, J., & Trachsel, M. (2023). Conversational artificial intelligence in psychotherapy: A new therapeutic tool or a potential risk? *The American Journal of Bioethics*, *23*(5), 4–13. https://doi.org/10.1080/15265161.2022.2048739

harmful advice is provided or what information influences them. The lack of transparency can make chatbot- generated interpretations appear more authoritative than they are. Clear disclosure is crucial, namely, informing users that they are interacting with AI, along with information about its limitations and data practices. Simultaneously, developers and organizations deploying these systems should establish clear accountability mechanisms for monitoring harmful outputs, ensuring appropriate human oversight and addressing errors[43]. Transparency and accountability are especially essential when AI- mediated reframing can influence users' psychological perspectives on significant decisions.

3.8 Research Gaps

Although research on conversational AI, human- AI interaction and digital mental health has expanded noticeably, the specific process through which AI chatbots shape user perspectives through cognitive reframing remains insufficiently understood. Several important gaps exist in the current literature.

3.8.1 Limited Direct Evidence on Cognitive Reframing

Existing studies have examined chatbot- based mental health interventions, user satisfaction and emotional support, but comparatively fewer studies directly examine cognitive reframing as a mechanism of AI influence. There is a need to distinguish between general supportive conversation and genuine changes in users' interpretation of thoughts, beliefs and events.

3.8.2 Lack of Longitudinal Research

Most existing research evaluates users immediately after short- term or limited chatbot interactions. Eventually, little is known about whether AI- mediated reframing produces sustained changes in beliefs, decision- making, self- perception or behaviour. Longitudinal studies are required to determine whether repeated exposure produces adaptive cognitive flexibility or unintended dependence and influence.

3.8.3 Insufficient Research on User Susceptibility

The influence of chatbot- generated reframing is unlikely to be uniform across individuals. Inadequately explored factors such as trust in AI, psychological characteristics, prior beliefs, emotional state, digital literacy and perceived credibility may determine how strongly users accept AI- generated perspectives.

3.8.4 Limited Cross- Cultural Evidence

Much of the existing literature originates from Western and technologically developed contexts. Cognitive interpretations, communication styles, perceptions of authority and emotional expressions may vary across cultures. Hence, more research is required to determine whether AI- reframing operates similarly across these different cultural, social and linguistics contexts specifically in culturally diverse settings such as India.

3.8.5 Absence of Standardized Measures

There is currently limited consensus on how to measure AI- mediated cognitive reframing and subsequent perspective change. Existing studies frequently depend on measures of user satisfaction, trust, engagement or symptom reduction instead of assessing changes in cognitive interpretation directly. Developing validated measures of reframing, perspective change and susceptibility to AI influence would strengthen empirical research in this area.

3.8.6 Limited Understanding of the Boundary between Support and Influence

A major unresolved issue is determining when helpful cognitive reframing becomes a covert persuasion or manipulation. AI systems can simultaneously validate users, influence decisions and challenge their assumptions. Future research is necessary to examine this boundary and identify design principles that promote beneficial perspective change while preserving user autonomy, informed choice and critical thinking.

3.8.7 Need for Interdisciplinary Research

This phenomenon cannot be adequately examined from a technological or psychological perspective alone. Future research should integrate clinical psychology, cognitive psychology, communication, AI ethics, human- computer interaction and behavioural science to develop a comprehensive understanding of how conversational AI influences human cognition.

IV. RESULTS: NARRATIVE SYNTHESIS OF THE LITERATURE

The synthesis of the literature indicates that AI chatbots are increasingly constructing as more than information- providing technologies. Their conversational capabilities enable them to participate in processes of reflection, emotional appraisal, decision- making and interpretation. Across the literature, five interconnected themes emerged: Cognitive reframing, emotional influence, perspective formation, behavioural and decision- making influence and the dual potential for support and manipulation.

4.1 AI Chatbots as Facilitators of Cognitive Reframing

The literature indicates how conversational AI can facilitate elements of cognitive reframing through reflective questioning, personalized feedback, alternative perspectives generation and emotional validation. These mechanisms resemble techniques used in cognitive- behavioural interventions, especially guided discovery and cognitive restructuring. Chatbots can encourage users to reconsider the automatic interpretations and examine situations from multiple perspectives, rather than simply providing solutions.

4.2 Influence on User Perspectives

A consistent pattern across the literature is that conversational AI can influence our users' interpretation of information and personal experiences. By selecting specific explanations, presenting alternative viewpoints and emphasizing certain aspects of a situation, chatbots may alter the cognitive frame through which users evaluate a problem.

This influence appears to be particularly relevant when users approach AI with uncertainty or limited prior knowledge. Conversational fluency, perceived competence, responsiveness and personalization may increase the credibility of AI- generated perspectives. Eventually, the impact of conversational AI may occur not only at the level of the final decision but much earlier, that is during the process through which users define and interpret the problem itself.

4.3 Emotional and Psychological Influence

The literature suggests that emotional validation and perceived empathy can increase user engagement with conversational systems. When users feel acknowledged, they may become more receptive to subsequent suggestions or alternative interpretations. Simultaneously, the literature emphasizes an important limitation that is simulated empathy should not be equated with human therapeutic empathy. The ability of AI to generate emotionally appropriate language does not imply genuine emotional understanding or clinical judgment. Therefore, perceived emotion may increase the influence of chatbots while creating risks of over- trust and anthropomorphism.

4.4 Influence on Decision- Making and Behaviour

Studies indicate that AI- mediated reframing may indirectly influence decision- making by changing our users conceptualize risks, available choices and consequences. Chatbots can broaden problem representations by introducing alternatives, encouraging users to consider different perspectives and identifying overlooked factors. This influence can be beneficial when it promotes critical reflection and more comprehensive decision- making. Nevertheless, it may become problematic when users accept AI-generated recommendations without independent evaluation. Hence AI should function as a decision-support mechanism rather than a decision- making authority.

4.5 Emerging Conceptual Relationship: From Advice to Influence

The central finding on the narrative synthesis is that the role of conversational AI can be conceptualized as a progression:

Information→ Advice→ Cognitive Reframing→ Perspective Change→ Decision/ Behavioural Influence

Primarily traditional information systems provide information whereas conversational AI interprets information within the context of an individual users concerns. When system provides alternative interpretations, it moves from advice toward cognitive reframing. If the reframed interpretation subsequently effects how the user understands the situation, change in perspective may occur. This altered perspective can then influence attitudes, behavioural intentions and decisions.

This progression underscores the reason behind psychological influence of conversational AI warrants

examination beyond conventional measures of accuracy and user satisfaction. This critical issue is not merely whether an AI chatbot provides useful advice, but whether the way that advice is framed changes how users think about themselves, circumstances and others.

4.6 Overall Narrative Findings

The literature supports the potential of AI chatbots to act as cognitive intermediaries capable of influencing user perspectives through conversational reframing. Nevertheless, the evidence remains heterogeneous, with substantial variation in chatbot design user populations, application domains and outcome measures. Direct empirical evidence examining cognitive reframing as a distant mechanism of AI influence remains comparatively limited.

The findings support a cautious interpretation: AI chatbots have the capacity to facilitate adaptive perspective change, but the same mechanisms can also reinforce bias, produce undue influence or increase dependence. The conversational AI may have psychological impact that is determined by what information is provided, how information is, how critically the evaluators responses and how users perceive the system. Moreover, cross- cultural, longitudinal and experimentally controlled research is required to establish the conditions under which AI-mediated cognitive reframing produces beneficial versus potentially harmful changes in user perspectives.

V. IMPLICATIONS FOR THEORY AND PRACTICE

The findings of this narrative review have implications for both the theoretical understanding of human- AI interaction and the practical development and use of conversational AI. The literature suggests that AI chatbots should not be conceptualized solely as information- delivery tools since their conversational characteristics allow them to participate in user's cognitive emotional processes.

5.1 Theoretical Implications

This narrative review extends existing perspectives on cognitive reframing and human- AI interaction by emphasizing on conversational AI as a potential cognitive intermediary. Traditional models of cognitive reframing primarily examine interaction between individuals and human therapists, social supports or counsellors. The findings suggest that some recently mechanisms such as reflect a questioning, cognitive restructuring prompts and alternative perspective generation, can also occur with human- AI conversations.

This review also provides a link between cognitive reframing, persuasive technology and CASA theory. When users perceive chatbots as credible, socially engaging and responsive, AI- generated perspectives may require greater psychological influence. This suggests that the effectiveness and influence of AI cannot be understood solely through its technical capabilities and that the users' perceptions of the are equally important.

5.2 Implications for AI Design and Mental Health Practice

Systems intended for psychological support should be designed to promote cognitive flexibility instead of a simple agreement. Chatbots should be capable of challenging assumptions that aren't helpful, communicating uncertainty, presenting balanced alternatives and distinguishing emotional validation from confirmation of a user's interpretation. Personalization should similarly be balanced with user autonomy to prevent excessive persuasion, dependency or reinforcement beliefs.

In mental health practice, conversational AI the serves as an adjunctive tool for psychoeducation, emotional declaration, low intensity cognitive behavioural support and self- reflection. Its accessibility and continuous availability may complement professional services, especially where access to mental health support is limited. Nevertheless, AI- generated cognitive reframing should not be considered equivalent to professional psychological intervention. Human professionals remain essential for assessment, diagnosis, risk evaluation, complex clinical decision-making and individualized treatment. Hence, mental health-oriented air systems should incorporate clear boundaries, escalation mechanisms and appropriate referral pathways for situations requiring human intervention.

5.3 Implications for Users and Digital Literacy

The results emphasize the significance of AI literacy and critical engagement. Users should understand that fluent and empathetic advert responses do not

necessarily indicate accuracy, expertise or genuine emotional understanding. User should be able to treat AI- generated interpretations as perspectives instead of authoritative conclusions. This is essential when is used for significant personal, educational, health or professional decisions. Developing users' ability to question, compare and verify AI- generated information may reduce automation bias in preserve independent judgment.

5.4 Implications for Policy and Governance

The rapid psychological influence of conversational A may require governance frameworks that address data protection, technical safety as well as psychological influence and user autonomy. Developers and organizations should establish standards for transparency, disclosure of AI involvement, monitoring harmful outputs, privacy, appropriate human oversight and accountability.

Psychologically vulnerable individuals and high- stake domains should be given high priority or higher attention. Regulatory and ethical frameworks should distinguish between beneficial personalization and manipulative personalization, especially when systems are capable of adapting their communication to influence individual users.

5.5 Implications for Future Research

Future research should investigate whether chatbot-generated reframing produces measurable changes in beliefs, emotion responses, cognitive flexibility, behaviour and decision- making. Longitudinal studies are necessary to determine whether repeated interactions produce sustained benefits or unintended dependency.

Research should also examine individual and cultural differences in susceptibility to AI mediated influence and develop standardized measures for assisting cognitive reframing and perspective change. Interdisciplinary collaboration between psychology, AI, human- AI interruption, ethics and behavioural science will be crucial for developing a comprehensive understanding of this emerging phenomenon.

Overall, the practical implication of the review is that conversational AI should not designed just to be helpful and engaging rather it should be reflective, transparent, psychologically responsible and autonomy- preserving.

VI. CONCLUSION

The present narrative review examined how AI chatbots are evolving from information- providing systems into conversational technologies capable of influencing users' interpretations, decision- making and perspectives through cognitive reframing. The literature indicates that mechanisms such as reflective questioning, alternative perspective generation, emotional validation, iterative dialogue and personalization enable conversational AI to participate in processes that are associated with human cognitive and traditionally associated with human support.

The review suggests that cognitive reframing represents a significant pathway through which AI-generated conversations may influence users. By changing how individuals interpret an event, personal experience or a problem, chatbots may indirectly influence emotional responses, behavioural intentions, attitudes and decisions. This influence can have beneficial applications in mental health support, healthcare, education, career guidance, everyday decision- making and interpersonal problem- solving. AI assistance can provide accessible opportunities for reflection and encourage users to consider perspectives that may be overlooked otherwise.

Nevertheless, the same mechanisms that make conversational AI useful also create significant ethical concerns. Algorithmic bias, persuasive manipulation, insufficient transparency and accountability, hallucinations, loss of human judgment, dependency, and privacy concerns may undermine user autonomy and psychological well- being. The central concern is therefore not whether AI chatbots influence users, rather whether that influence is accurate, transparent, autonomy- preserving, beneficial and voluntary. The review further underscores the transition from 'advice' to 'influence'. While traditional advice provides information that users can evaluate, cognitive reframing can alter the interpretive framework through which users subsequently understand information and make decisions. This sets conversational AI fundamentally apart from conventional information-retrieval technologies and warrants greater attention from technological, psychological and ethical perspectives.

Ultimately, AI chatbot should not be viewed simply as neutral tools for delivering information. Their language, responsiveness, perceived social qualities

and personalization give them the capacity to shape how users think and interpret their experiences. The future development of conversational AI, hence, prioritizes critical thinking, transparency, human autonomy, responsible influence and psychological safety while ensuring that AI supports users in developing their own perspectives instead of determining those perspectives for them.
