An Efficient Scalable Framework for Auto Scaling Services in Cloud Computing Environment

Pranali Gajjar, Brona Shah
Silver Oak College of Engineering and Technology, Gujarat Technological University, S. G. Highway, Gota, Ahmedabad, India

Abstract- Cloud computing is a recent technology trending that help companies in providing their services in a scalable manner. Hence, used this service capabilities required many procedures in order to get better performance. Cloud computing environments allow customers to dynamically scale their applications. The key problem is how to lease the right amount of resources, on a pay-as-you-go basis. The objective of this paper was to present a comprehensive study about the auto-scaling mechanisms available today. Auto-scaling techniques are diverse, and involve various components at the infrastructure, platform and software levels. Many techniques have been proposed for auto-scaling. We propose a classification of these techniques into five main categories: static threshold-based rules, control theory, reinforcement learning, queuing theory and time series analysis.

Index Terms- Cloud Computing, Auto scaling, Auto scaling techniques

I. INTRODUCTION OF CLOUD COMPUTING

Cloud computing is in its infant form and numerous definitions have been proposed by many scientists. Some of the definitions are, Buyya et al. defines, “A Cloud is a type of parallel and distributed system consisting of a collection of inter-connected and virtualized computers that are dynamically provisioned and presented as one or more unified computing resource(s) based on service-level agreements established through negotiation between the service provider and consumers” [1]. The National Institute of Standards and Technology (NIST) defines, “A model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. This cloud model promotes availability and is composed of five essential characteristics, three service models, and four deployment models” [2].

Figure 1: Cloud Computing

1.1 Characteristics of Cloud

- **On Demand Self Service:** On demand self-service refers to services requested by the customers to manage their own computing resources. These services are provided over the internet by a cloud provider to a customer who has requested for services and can manage their own computing resources.
- **Resource Pooling:** Cloud computing provides shared pool of resources that can be rapidly provisioned and can be released with minimal effort. Customers draw resources from remote data centers.
- **Broad Network Access:** To avail cloud computing services, internet works as a backbone of cloud computing. All services are available over the network and are also accessible through standard protocols using web enabled devices viz. computers, laptops, mobile phones etc.
- **Rapid Elasticity**: As cloud computing provides services over the internet. These services can be managed or can be requested from cloud providers as per customer’s requirement. Rapid elasticity refers to services which can be smaller or larger as per user requirement.

- **Measured Service**: These are services which are billed according to customer demand for definite services. As customers can request for services as per their own requirement, services are billed according to customer’s demand.

### 1.2 Service Models of Cloud Computing

Cloud computing is a computational process in which services are delivered over a network using computing resources. The name ‘cloud’ symbolizes an abstraction for complex infrastructure it contains in system diagrams.

![Service Model](image)

**Figure 2: Service Model**

- There are three main types of service models:
  - Software as a Service (SaaS)
  - Platform as a Service (PaaS)
  - Infrastructure as a Service (IaaS)

#### 1.2.1 Software-as-a-Service (SaaS):

In this multitenant service model, the consumers use application running on a cloud infrastructure. The cloud infrastructure including (servers, OS, Network or application etc.) is managed and controlled by the service provider with the user not having any control over the infrastructure. Some of the popular examples are SalesForce.com, NetSuite, IBM, Microsoft and Oracle etc.

Example for SaaS Company:
- Athenahealth
- Concur Technologies
- E2open

#### 1.2.2 Platform-as-a-Service (PaaS):

With this model, the provider delivers to user a platform including all the systems and environments comprising software development life cycle viz. testing, deploying, required tools and applications. The user does not have any control over network, servers, operating system and storage but it can manage and control the deployed application and hosting environments configurations. Some popular PaaS providers are GAE, Microsoft’s Azure etc.

Example for PaaS Company:
- Apprenda
- IBM
- Open shift

#### 1.2.3 Infrastructure-as-a-Service (IaaS):

In this service model, the provider delivers to user the infrastructure over the internet. With this model, the user is able to deploy and run various software’s including system or application softwares. The user has the ability to provision computing power, storage, networks. The consumers have control over operating systems, deployed applications, storage and partial control over network. The consumer has no control over underlying infrastructure. Some important IaaS providers are GoGrid, Flexiscale, Joyent, Rackspace etc.

Example for IaaS Company:
- Amazon web service
- At & t
- Ca technologies

### 1.3 Deployment models

Cloud systems can be deployed in four forms viz. private, public, community and hybrid cloud as per the access allowed to the users and are classified as follows:

#### 1.3.1 Private cloud:

This deployment model is implemented solely for an organization and is exclusively used by their employees at organizational level and is managed and controlled by the organization or third party. The cloud infrastructure in this model is installed on premise or off premise. In this deployment model, management and maintenance are easier, security is very high and organization has more control over the infrastructure and accessibility.

Examples of Private Cloud:
1.3.2 Public cloud:
This deployment model is implemented for general users. It is managed and controlled by an organization selling cloud services. The users can be charged for the time duration they use the services. Public clouds are more vulnerable to security threats than other cloud models because all the application and data remains publicly available to all users making it more prone to malicious attacks. The services on public cloud are provided by proper authentication.

Examples of Public Cloud:
- Google App Engine
- Microsoft Windows Azure
- IBM Smart Cloud
- Amazon EC2

1.3.3 Community cloud:
This cloud model is implemented jointly by many organizations with shared concerns viz. security requirements, mission, and policy considerations. This cloud is managed by one or more involved organizations and can be managed by third party. The infrastructure may exist on premise to one of the involved organization or it may exist off premise to all organizations.

Examples of Community Cloud:
- Google Apps for Government
- Microsoft Government Community Cloud

1.3.4 Hybrid cloud:
This deployment model is an amalgamation of two or more clouds (private, community, public or hybrid). The participating clouds are bound together by some standard protocols. It enables the involved organization to serve its needs in their own private cloud and if some critical needs (cloud bursting for load-balancing) occur they can avail public cloud services.

Examples of Hybrid Cloud:
- Windows Azure (capable of Hybrid Cloud)
- VMware vCloud (Hybrid Cloud Services)

1.4 Advantages of Cloud Computing
Cloud computing offers many benefits and flexibility to its users. User can operate from anywhere at any
time in a secure way. With the increasing number of web-enabled devices used now-a-days (e.g. tablets, smart phones etc.), access to one’s information and data must be quick and easier. Some of these relevant benefits in respect to the usage of a cloud can be as follows:

- Reduces up-front investment, Total Cost of Ownership (TCO), Total Operational Cost (TOC) and minimizes business risks.
- Provides a dynamic infrastructure that provides reduced cost and improved services with less development and maintenance cost.
- Provides on-demand, flexible, scalable, improved and adaptable services on pay-as-you go model.
- Provides consistent availability and performance with automatically provisioned peak loads.
- Can recover rapidly and has improved restore capabilities for improved business resiliency.
- Provides unlimited processing, storage, networking etc. in an elastic way.
- Offers automatic software updates, Improved Document Format Compatibility and improved compatibility between different operating systems.
- Offers easy group collaboration i.e. flexibility to its users on global scale to work on the same project.
- Offers increased return on investment of existing assets, freeing capital to deploy strategically.
- Provides environment friendly computing as it only uses the server space required by the application which in turn reduces the carbon footprints.

1.5 Disadvantages of Cloud Computing

Every coin has two faces. That’s not to say, of course, cloud computing is without disadvantages. Some of the disadvantages while using a cloud can be summarized as:

- Requires high speed network and connectivity constantly.
- Privacy and security is not good. The data and application on a public cloud might not be very secure.
- Disastrous situation are unavoidable and recovery is not possible always. If the cloud loses one’s data, the user and the service provider both gets into serious problems.
- Users have external dependency for mission critical applications.
- Requires constantly monitoring and enforcement of service level agreements (SLAs).

II. DEFINING SCALABILITY

Today, cloud computing is totally revolutionizing the way computer resources are allocated, making it possible to build a fully scalable server setup on the Cloud. If your application needs more computing power, you now have the ability to launch additional compute resources on-demand and use them for as long as you want, and then terminate them when they are no longer needed. In cloud computing applications with a dynamic workload demand need access to a flexible infrastructure to meet performance guarantees and minimize resource costs. While cloud computing provides the elasticity to scale the infrastructure on demand, cloud service providers lack control and visibility of user space applications, making it difficult to accurately scale the underlying infrastructure. Thus, the burden of scaling falls on the user. With cloud computing, the end user usually pays only for the resource they use and so avoids the inefficiencies and expense of any unused capacity. Many Internet applications can benefit from an automatic scaling property where their resource usage can be scaled up and down automatically by the cloud service provider.

“AUTO-SCALING AUTOMATES THE EXPANSION OR CONTRACTION OF SYSTEM CAPACITY THAT IS AVAILABLE FOR APPLICATIONS AND IS A COMMONLY DESIRED FEATURE IN CLOUD IAAS AND PaaS OFFERINGS. WHEN FEASIBLE, TECHNOLOGY BUYERS SHOULD USE IT TO MATCH PROVISIONED CAPACITY TO APPLICATION DEMAND AND SAVE COSTS.” In Amazon Web Service (AWS), auto-scaling is defined as a cloud computing service feature that allows AWS users to automatically launch or terminate virtual instances based on defined policies, health status checks, and schedules. Meanwhile, In RightScale, auto-scaling is defined as “a way to automatically scale up or down the number of compute resources that are being allocated to your application based on its needs at any given time.” From an academic point of view, auto-scaling is the capability in cloud computing
infrastructures that allows dynamic provisioning of virtualized resources. Resources used by cloud based applications can be automatically increased or decreased, thereby adapting resource usage to the applications’ requirements [6].

Auto Scaling helps you ensure that you have the correct number of EC2 instances available to handle the load for your application. You create collections of EC2 instances, called Auto Scaling groups. You can specify the minimum number of instances in each Auto Scaling group, and Auto Scaling ensures that your group never goes below this size. You can specify the maximum number of instances in each Auto Scaling group, and Auto Scaling ensures that your group never goes above this size. If you specify the desired capacity, either when you create the group or at any time thereafter, Auto Scaling ensures that your group has this many instances. If you specify scaling policies, then Auto Scaling can launch or terminate instances as demand on your application increases or decreases [6].

For example, the following Auto Scaling group has a minimum size of 1 instance, a desired capacity of 2 instances, and a maximum size of 4 instances. The scaling policies that you define adjust the number of instances, within your minimum and maximum number of instances, based on the criteria that you specify [6].

Figure 9: Autoscaling

Based on these definitions, the key features of auto-scaling are:
- The ability to scale out (i.e., the automatic addition of extra resources during increased demand) and scale in (i.e., the automatic termination of extra unused resources when demand decreases, in order to minimize cost).
- The capability of setting rules for scaling out and in.
- The facility to automatically detect and replace unhealthy or unreachable instances.

2.1 Benefits of Auto Scaling:
Adding Auto Scaling to your application architecture is one way to maximize the benefits of the AWS cloud. When you use Auto Scaling, your applications gain the following benefits:

- Better fault tolerance. Auto Scaling can detect when an instance is unhealthy, terminate it, and launch an instance to replace it.
- Better availability. You can configure Auto Scaling to use multiple Availability Zones. If one Availability Zone becomes unavailable, Auto Scaling can launch instances in another one to compensate.
- Better cost management. Auto Scaling can dynamically increase and decrease capacity as needed. Because you pay for the EC2 instances you use, you save money by launching instances when they are actually needed and terminating them when they aren't needed.

III. CLASSIFICATION OF AUTO SCALING TECHNIQUES

It is difficult to work out a proper classification of auto-scaling techniques, due to the wide diversity of approaches found in the literature that are sometimes hybridizations of two or more methods. Considering the anticipation capacity as the main criteria, techniques could be divided into two main classes: reactive (the system reacts to changes but does not anticipate them) or predictive (the system tries to predict future resource requirements in order to ensure sufficient resource are available ahead of time) [7].

3.1 Reactive Scaling:
Reactive scaling is also implemented. When a company begins running applications in cloud resources, some unexpected changes in the workload may occur. A reactive scaling strategy can meet this demand by adding or removing scaling up or down resources. Periodic acquisition of performance data is important both to the cloud provider and to the cloud agencies for maintaining QoS. In addition, reactive scaling enables a provider to react quickly to unexpected demand. In other words, when CPU or RAM or another resource reaches a certain level of utilization, the provider adds more of that resource to the environment.
3.2 Proactive Scaling:
Proactive scaling is usually done in a cloud by scaling at predictable, fixed intervals or when big surges of traffic requests are expected. Proactive scaling is also known as predictive scaling. A well-designed proactive scaling system enables providers to schedule capacity changes that match the expected changes in application demand. To perform proactive scaling, they should first understand expected traffic flow. This simply means that they should understand (roughly) how much normal traffic deviates from agency expectations. The most efficient use of resources is just below maximum agency capacity, but scheduling things that way can create problems when expectations are wrong.

IV. PROPOSED SYSTEM

4.1 Problem Statement
These days cloud computing is getting to be a standout amongst the most utilized innovative answer for accomplish adaptability and decrease costs. Scalability is a key purpose for the accomplishment of any business involving the web and providing services to end-user requests which will vary drastically from just once to a different. Measuring a system to provide performance guarantees under peak traffic can be cost restrictive. Auto-scaling is responsible for adjusting the amount of accessible resources to fulfill service demand. The effectiveness of auto-scaling in term of the reliability of the auto-scaling process is not well managed. Failure of the auto-scaling process will result in violations of the system’s QoS requirements of performance and scalability and even incur unnecessary cost.

4.2 Proposed System
In our work, we will build recommendation system for auto-scaling using Infrastructure as a code, it is essential to maintain a scalable framework. The framework includes major components:
- Load Balancer
- Request Mapper
  - Request Queue
  - Request Creator
- VM Mapper
  - VM Information Engine
  - VM Queue
- Recommendation Engine
- Template Selector
- Container Executor

Request Mapper:
- Request will received by the Load Balancer.
- Request Array to Request Queue.
- Request Formator will get Request from Request Queue.
- Request Formator will select VM for request from VM Queue.
- Request Formator reformate request as per VM address.
- Request Formator forward new request to selected VM Queue.

VM Information Engine:
- VM Information Engine will fetch the information about VM periodically (manual set) like CPU Utilization, IP Address.
- VM Information Engine will store that information of each VM in temp memory.

Recommendation Engine:
- Recommendation Engine will receive this information from VM Information Engine.
- Recommendation Engine calculate container add + or remove – using fetch information and threshold value.
- Respected Container add + or remove – will call. This wills effort of particular template.

VM Queue Creator:
- VM Queue will generate based on fetch information (CPU Utilization, Memory).

4.3 Proposed Algorithm

Step 1: Request Mapper();
  <Request Queue> ➔ Load Balancer
Step 2: Request Queue();
  <Request Formator> ➔ <Request Queue>
Step 3: Request Formator();
  <VM Queue> ➔ Select VM ➔ <Request Formator>
  <VM Queue> ➔ Request ➔ <Request Formator>
Step 4: VM Information Engine();
  Temp Memory ➔ Store ➔ <VM Information Engine>
Step 5: VM Queue().
Fetch the Information
<VM Information Engine >

Calculate CPU Utilization:
If \( x > \text{thrUp} \) for \( \text{vUp} \) seconds then
\( n = n + s \) and
Do nothing for \( \text{inUp} \) seconds
Else If \( x < \text{thrDown} \) for \( \text{vDown} \) second then
\( n = n - s \) and
Do nothing for \( \text{inDown} \) seconds
Else \( n = n \)
No operation
Where, \( \text{thrUp} \) = a upper threshold
\( \text{thrDown} \) = a lower threshold
\( \text{vUp} \) and \( \text{vDown} \) = two time values for
define how long condition must be met to trigger a
scaling action
\( \text{inUp} = \text{scaling up} \)
\( \text{inDown} = \text{scaling down} \)
\( s \) = Amount of VM allocated or deallocated or
Resource will added or remove
Step 6:
<Recommendation System >
<VM Information Engine >
Step 7: Container Executer ();
Calculate Container, if add + or remove –
Step 8: Select Template and Add + container
Step 9: If container removes –
Terminate container
Step 10: Goto Step 5

V. CONCLUSION

One of the conclusions that can be extracted from this
survey is that auto scaling is the ability to scale up or
down the capacity automatically according to
conditions of the user defines. With Auto Scaling
ensure that the number of instances is increasing
seamlessly during demand to maintain performance,
and decreases automatically during demand reduce to
minimize costs. The system should be able to adapt
to the customer request so as to increase resources or
decrease the resources, so as to maintain the balance
between performance and cost effectiveness. We
discussed various types of scaling. Here we have
discussed the auto scaling techniques. Improving
the performance and utilization of the cloud systems are
gained by the auto-scaling of the applications; this is
because of the fact that, some approaches have been
proposed for auto scaling.
