Abstract-The *W*-energy of a semigraph G is the sum of the absolute values of its *W*-eigenvalues. In this paper we show that the graph energy of the classes of paths and cycles is more than the *W*-energy of the semigraphs when some vertices are replaced by middle vertices.

AMS Subject classification: 05C50, 05C99

Keywords: Weighted adjacency matrix; *W*-Energy; *W*-Characteristic polynomial.

#### 1. INTRODUCTION

The concept of semigraph is a natural generalization of the graph introduced by E. Sampathkumar [7] wherein an edge may contain more than two vertices having middle vertices apart from the usual end vertices. A semigraph *G* is a pair (*V*, *X*), where *V* is a non-empty set whose elements are called vertices of *G* and *X* is a set of ordered *n*-tuples called edges of *G* of distinct vertices, for various  $n \ge 2$ , satisfying the following conditions:

SG1: Any two edges have at most one vertex in common.

SG2: Two edges  $(u_1, u_2, ..., u_m)$  and  $(v_1, v_2, ..., v_n)$  are equal if and only if

(i) m = n and

(ii) either  $u_i = v_i$  or  $u_i = v_{n-i+1}$  for  $1 \le i \le n$ .

Thus the edge  $(u_1, u_2, \dots, u_n)$  is the same as  $(u_n, u_{n-1}, \dots, u_1)$ .

If  $E = (v_1, v_2, ..., v_n)$  is an edge of a semigraph, we say that  $v_1$  and  $v_n$  are the *end* vertices of edge *E* and  $v_i$  for  $2 \le i \le n - 1$  are the middle vertices or *m*vertices of the edge *E* and also the vertices  $v_1, v_2, ..., v_n$  are said to belong to the edge *E*. Two vertices *u* and  $v, u \ne v$ , in a semigraph are adjacent if both of them belong to the same edge.

An edge containing at least one *m*-vertex is called an *S*-edge, otherwise it is called an ordinary edge. A semigraph with *p* vertices and *q* edges is called a (p,q) semigraph. A partial edge of an edge  $E = (v_{i_1}, v_{i_2}, ..., v_{i_n})$  is a (k - j + 1) tuple E' =

 $(v_{i_j}, v_{i_{j+1}}, \dots, v_{i_k})$  where  $1 \le j < k \le n$ . We say that, the partial edge E' has cardinality k - j + 1, which we again denoted by |E'|. A subedge of an edge E = $(v_{i_1}, v_{i_2}, \dots, v_{i_n})$  is a k-tuple  $E' = (v_{i_{j_1}}, v_{i_{j_2}}, \dots, v_{i_{j_k}})$ where  $1 \le j_1 < j_2 < \dots < j_k \le n$ .

The number of vertices belonging to an edge *E* is called the cardinality of *E* and is denoted by |E|. A partial edge of cardinality 2 is called a unit partial edge. The length of an edge *E* is the number of unit partial edges of the edge *E* and is denoted by l(E). Thus if  $E = (v_1, v_2, ..., v_k)$  then l(E) = k - 1 and |E| = k. The length of a partial edge is defined similarly. If the vertices u, v are adjacent, then (u, ..., v) is a partial edge whose length is denoted by l(u, v).

Three vertices  $v_i, v_j$  and  $v_k$  are said to form a triangle in a semigraph *G*, if they are pairwise adjacent but do not lie on the same edge. If the vertices  $v_i, v_j$  and  $v_k$ form a triangle in a semigraph then the partial edges  $(v_i, ..., v_j), (v_j, ..., v_k)$  and  $(v_k, ..., v_i)$  are called the sides of the triangle.

Let *G* be a simple graph with *k* vertices and *A*(*G*) be its adjacency matrix. Let  $\lambda_1, ..., \lambda_k$  be the eigenvalues of *A*(*G*). Then the *energy* of *G* [2], denoted by *E*(*G*), is defined as  $E(G) = \sum_{i=1}^{k} |\lambda_i|$ . The energy of the cycle  $C_k$  and the path  $P_k$  are given by

$$E(C_k) = \begin{cases} \frac{4\cos\frac{\pi}{k}}{\sin\frac{\pi}{k}}, & \text{if } k \equiv 0 \pmod{4}; \\ \frac{4}{\sin\frac{\pi}{k}}, & \text{if } k \equiv 2 \pmod{4}; \\ \frac{2}{\sin\frac{\pi}{2k}}, & \text{if } k \equiv 1 \pmod{2}. \end{cases}$$

$$E(P_k) = \begin{cases} \frac{2}{\sin \frac{\pi}{2(k+1)}} - 2, & \text{if } k \equiv 0 \pmod{2}; \\ \frac{2\cos \frac{\pi}{2(k+1)}}{\sin \frac{\pi}{2(k+1)}} - 2, & \text{if } k \equiv 0 \pmod{2}. \end{cases}$$

A semigraph may have edges having several vertices including possible middle vertices apart from two end vertices. The *L*-adjacency matrix  $L(G) = (l_{ij})$  of a semigraph *G* was defined in [6] to reflect this aspect by defining

 $l_{ij}$ 

 $= \begin{cases} 0, & \text{if } v_i \text{ and } v_j \text{ are not adjacent or } v_i = v_{j_i} \\ l(v_i, v_j) & \text{if } v_i \text{ and } v_j \text{ are adjacent,} \end{cases}$ 

where two vertices  $v_i$  and  $v_j$  are adjacent if they belong to the same edge.

Given a (p, q)-semigraph G, we define its weighted adjacency (or W-adjacency) matrix  $W(G) = (w_{ij})$ , where

$$\begin{split} & w_{ij} \\ &= \begin{cases} 0, & \text{if } v_i \text{ and } v_j \text{ are not adjacent or } v_i = v_j; \\ &= \begin{cases} \frac{l(v_i, v_j)}{k} & \text{if } v_i \text{ and } v_j \text{ are adjacent lying on an edge of length } k. \\ & \text{Note that } W(G) \text{ is a symmetric } p \times p \text{ matrix with entries from } \mathbb{Q}, \text{ the field of rationals. Also, if } v_i, v_j \text{ are end vertices of an edge } E, \text{ then } w_{ij} = \frac{l(v_i, v_j)}{l(E)} = 1. \text{ Let } \mu_1, \dots, \mu_k \text{ be the eigenvalues of } W(G) \text{ (called } W\text{-eigenvalues). The } W\text{-energy } E_W(G) \text{ of the semigraph } G \text{ is the sum of the absolute values of its } W\text{-eigenvalues i.e., } E_W(G) = \sum_{i=1}^k |\mu_i|. \end{cases}$$

In section 2, we show that the graph energy of the classes of paths and cycles is more than the *W*-energy of the semigraphs when some vertices are replaced by middle vertices.

### 2. RESULTS

By introducing *m* number of middle vertices to each edge of the cycle  $C_n$ , the induced semigraph obtained is denoted by  $C_{n,m}$ . Similarly, by introducing *m* number of middle vertices to each edge of the path  $P_n$ , the induced semigraph obtained is denoted by  $P_{n,m}$ . We compare the energy of  $C_n$  and  $P_n$  with the *W*-energy of the induced semigraphs by making use of the upper bound for *W* energy of semigraphs obtained in Theorem. 3.7 of [5]: For a (p, q)-semigraph *G*, we have,  $E_W(G) \le \sqrt{-2ph_2}$ , where  $-h_2 = \sum_{E \in X} \frac{(|E|)^2(|E|+1)}{12(|E|-1)}$ .

Theorem 2.1: Suppose  $k \ge 9$  and  $k \equiv 3 \pmod{6}$ . Let  $C_{k/3,2}$  be the semigraph with k vertices having  $\frac{k}{3}$  number of edges each of cardinality 4 as shown below.

Then  $E_W(C_{k/3,2}) < E(C_k)$ .

Proof: By Theorem. 3.7 of [5], it is enough to show that  $E(C_k) > \sqrt{-2h_2k}$  as  $\sqrt{-2h_2k}$  is an upper bound for  $E_W(C_{k/3,2})$ , where  $-h_2$  is the coefficient of  $\eta^{k-2}$ in the *W*-characteristic polynomial of  $C_{k/3,2}$  is given by  $-h_2 = \sum_{E \in X} \frac{|E|^2(|E|+1)}{12(|E|-1)}$ . Now, the semigraph  $C_{k/3,2}$  has  $\frac{k}{3}$  number of edges each edge of cardinality 4 and so, we have,

$$-h_2 = \frac{k}{3} \times \frac{16 \times 5}{12 \times 3} = \frac{20}{27}k$$

and so

$$\sqrt{-2h_2k} = \sqrt{2 \times \frac{20k}{27} \times k} = k \sqrt{\frac{40}{27}}$$

Since k is odd,  $E(C_k) = \frac{2}{\sin \frac{\pi}{2k}}$  and so it is enough to show  $\frac{2}{\sin \frac{\pi}{2k}} > k \sqrt{\frac{40}{27}}$  for all  $k \ge 9$  and  $k \equiv 3 \pmod{6}$ . We prove that  $\frac{1}{\sin \frac{\pi}{2x}} > \frac{x}{3} \sqrt{\frac{10}{3}}$  for all  $x \ge 9$ . Put  $t = \frac{\pi}{2x}$ . Then  $\frac{x}{3} \sqrt{\frac{10}{3}} = \frac{\pi}{6t} \sqrt{\frac{10}{3}} = \frac{\alpha}{t}$ , where  $\alpha = \frac{\pi}{6} \sqrt{\frac{10}{3}} \approx 0.942$ . Now we need to show  $\frac{1}{\sin t} > \frac{\alpha}{t}$  for all  $t \le \frac{\pi}{18} = \gamma$ , where  $\gamma \approx 0.174$ . Since  $\sin t < t$  for all t > 0, we have,  $t > \sin t > \alpha \sin t$  for all t > 0as  $0 < \alpha < 1$ . Thus, we have,  $E_W(C_{k/3,2}) < E(C_k)$ , completing the proof of the theorem. Theorem 2.2: Suppose  $k \equiv 4 \pmod{6}$  and  $P_{\frac{k+2}{3},2}$  be the semigraph with *k* vertices having  $\frac{k-1}{3}$  number of edges each of cardinality 4 as given below:

**Fig. 2.2** Semigraph 
$$P_{\frac{k+2}{3},2}$$

Then 
$$E_W\left(P_{\frac{k+2}{3},2}\right) < E(P_k).$$

Proof: Using Theorem. 3.7 of [5], it is enough to show that  $E(P_k) > \sqrt{-2h_2k}$  as  $\sqrt{-2h_2k}$  is an upper bound for  $E_W\left(P_{\frac{k+2}{3},2}\right)$ , where  $-h_2$  is the coefficient of  $\eta^{k-2}$ in the *W*-characteristic polynomial of  $P_{\frac{k+2}{3},2}$  given by  $-h_2 = \sum_{E \in X} \frac{|E|^2(|E|+1)}{12(|E|-1)}$ . Since *k* is even, we have,  $E(P_k) = \frac{2}{\sin\frac{\pi}{2(k+1)}} - 2$ . Thus, it is enough to show that  $\frac{2}{\sin\frac{\pi}{2(k+1)}} - 2 > \sqrt{-2h_2k}$ . Now, the semigraph  $P_{\frac{k+2}{3},2}$ has  $\frac{k-1}{3}$  number of edges each of cardinality 4. If we put k = 6l + 4, then  $\frac{k-1}{3} = 2l + 1$  and so, we have,

$$-h_2 = (2l+1) \times \frac{16 \times 5}{12 \times 3} = (2l+1)\frac{20}{9}$$
$$= (6l+3)\frac{20}{27}$$

and so

$$\sqrt{-2h_2k} = \sqrt{(6l+3) \times \frac{40}{27} \times (6l+4)}$$
$$< (6l+4)\sqrt{\frac{40}{27}}$$

since 6l + 3 < 6l + 4. If we show that

$$E(P_k) = \frac{2}{\sin\frac{\pi}{2(6l+5)}} - 2 > (6l+4) \sqrt{\frac{40}{27}}$$

for all  $l \ge 2$ , then this would mean that  $E(P_k) >$ 

 $\sqrt{-2h_2k}$  for all k with  $k \ge 16$  and  $k \equiv 4 \pmod{6}$ .

We show that  $\frac{1}{\sin\frac{\pi}{2(6x+5)}} > 1 + (6x+4)\sqrt{\frac{10}{27}}$  for all  $x \ge 2$ . Put  $t = \frac{\pi}{2(6x+5)}$ . Then, we have,

$$1 + (6x + 4)\sqrt{\frac{10}{27}} = 1 + \left(\frac{\pi}{2t} - 1\right)\sqrt{\frac{10}{27}}$$
$$= \left(\sqrt{\frac{10}{27}} \times \frac{\pi}{2}\right)\frac{1}{t} + \left(1 - \sqrt{\frac{10}{27}}\right)$$
$$= \frac{\alpha}{t} + \beta, \text{ say,}$$
where  $\alpha = \frac{\pi}{t}\sqrt{\frac{10}{27}} \approx 0.055$  and  $\beta = 1$ .

where  $\alpha = \frac{\pi}{2} \sqrt{\frac{10}{27}} \approx 0.955$  and  $\beta = 1 - \sqrt{\frac{10}{27}} \approx 0.3915$ . Also as  $x \ge 2$ , we have,  $t = \frac{\pi}{2(6x+5)} \le \frac{\pi}{34} = \gamma$ , say, where  $\gamma \approx 0.09235$ .

Now,  $t > \sin t$  for all t > 0. Hence for  $0 < t \le \gamma$ , we have,

$$\frac{1}{\sin t} > \frac{1}{t} = \frac{\alpha}{t} + \frac{1-\alpha}{t},$$

where

$$\frac{1-\alpha}{t} \ge \frac{1-\alpha}{\gamma} > \beta,$$

as  $\frac{1-\alpha}{\gamma} \approx 0.484$ . Thus,

$$\frac{1}{\sin t} > \frac{\alpha}{t} + \beta \text{ for } t \in (0, \gamma]$$

Thus  $E(P_k) > E_W\left(P_{\frac{k+2}{3},2}\right)$  for all positive integers  $k \ge 16$  such that  $k \equiv 4 \pmod{6}$ .

For k = 4, 10 (that is when l = 0, 1), it can easily be checked to show the validity of the theorem and so this proves the theorem.
